

Nana's Mama Hostinger Setup Instructions

Use this guide to retrieve the Hostinger-ready project from GitHub, build it in VS Code, and upload it to Hostinger.

1. Get The Project From GitHub

1. Open VS Code.
2. Open the VS Code terminal.
3. Choose where to save the project, then run:

```
cd ~/Documents  
  
git clone https://github.com/gyebi/nanasmama-hostinger.git  
  
cd nanasmama-hostinger
```

2. Install And Build

1. Install dependencies:

```
npm install
```

2. Build the production website:

```
npm run build
```

The upload-ready website will be inside:

```
nanasmama-hostinger/dist
```

3. Upload To Hostinger

1. Log into Hostinger hPanel.
2. Open the correct website or domain.
3. Go to **Files** then **File Manager**.
4. Open the domain's **public_html** folder.
5. Delete Hostinger's default placeholder files, especially any old **index.html**.
6. Upload everything inside the local **dist** folder into **public_html**.

Important: upload the contents of **dist**, not the **dist** folder itself.

After upload, **public_html** should contain:

```
index.html  
products.html  
contact.html  
assets/  
sitemap.xml  
robots.txt
```

4. Domain And SSL

1. In Hostinger, confirm the domain points to the hosting account.
2. Enable SSL so the site loads with `https://`.
3. Test these URLs:

```
https://nanasmama.com/  
https://nanasmama.com/products.html  
https://nanasmama.com/contact.html  
https://nanasmama.com/sitemap.xml
```

5. Contact Form Email Note

The contact form uses Firebase to send email. Hostinger serves the static website, but Firebase handles the email request.

After upload, test the form here:

```
https://nanasmama.com/contact.html
```

1. Submit a small test message through the contact form.
2. Confirm the email arrives at `nanasmamashea@gmail.com`.
3. If the form does not send, check that the Firebase Function is deployed and the `RESEND_API_KEY` secret is configured.
